Daily Archives: July 29, 2013 Wells have been drilled in Vologda for oil, gas, shale gas, shale oil, sand and stone. A “spillage” oil well was drilled in a seismic test well in a shale field. According to the newspaper “Vologda Vedomosti”, the oil well was placed within a block of 8-10 wells. As it is known, the oil business still belongs to the Vologda region. The territory of the region is the largest oil and gas producing region of Russia. In Vologda oil fields, the “spillage” wells have been realized for a period of 30 years. It became possible with the improvement of the oil field technology, which allowed to drill “spillage” wells in areas of the oil fields where no oil wells were realized before. In a traditional oil well, a sealed bore hole is drilled and the bottom end of the bore hole is closed with a plug. The plug is filled with a special substance. As a result, any leaks are blocked. The waste products are not released into the environment. Oil is pumped into the bore hole from a well on the surface. The well, which cannot be worked, is left in the territory of the reserve. The “spillage” wells are drilled in the area of old oil wells. Oil is pumped into the bore hole through the old oil well. The oil enters the “spillage” well through an annulus between the pipe of the old oil well and a pipe of the new one. The oil enters a pipe of the “spillage” well at a lower point than the annulus. The “spillage” well is about a kilometer in length and about 6 meters in diameter. As a result, if it rains, the oil will run out of the “spillage” well into the territory of the reserve. The “spillage” well can be used to control the oil leakage in the reserve. In a “spillage” well
